Abstract

Video text spotting is crucial for numerous real application scenarios, but most existing video text reading benchmarks are challenging to evaluate the performance of advanced deep learning algorithms due to the limited amount of training data and tedious scenarios. To address this issue, we introduce a new large-scale benchmark dataset named **M**ultidimensional **M**ultilingual **V**ideo Text (MMVText), the first large-scale and multilingual benchmark for video text spotting in a variety of scenarios. There are mainly three features for MMVText. Firstly, we provide **510** videos with more than **1,000,000** frame images, four times larger than the existing largest dataset for text in videos. Secondly, our dataset covers 30 open categories with a wide selection of various scenarios, *e.g., life vlog, sports news, automatic drive, cartoon, etc*. Besides, caption text and scene text are separately tagged for the two different representational meanings in the video. The former represents more theme information, and the latter is the scene information. Thirdly, the MMVText provides multilingual text annotation to promote multiple cultures live and communication. In the end, a comprehensive experimental result and analysis concerning text detection, recognition, tracking, and end-to-end spotting on MMVText are provided. We also discuss the potentials of using MMVText for other video-and-text research. The dataset and code can be found at github.com/weijiawu/MMVText.

1 Introduction

Text spotting [23, 13] has received increasing attention due to its numerous applications in computer vision, e.g., document analysis, image-based translation, image retrieval [35, 28], etc. With the advent of deep learning and abundance in digital data, reading text from images has made extraordinary progress in recent years with a lot of great public datasets [9, 14, 6] and algorithms [45, 54, 24, 22]. By contrast, video text spotting almost remains at a standstill for the lack of large-scale multidimensional practical datasets, which limited numerous applications of video text, *e.g.,* video understanding [40], video retrieval [8], video text translation, and license plate recognition [1], etc.

Most existing algorithms [54, 45, 20] in text detection and recognition deal with only static frames. Therefore, one intuitive drawback of these approaches is that they do not necessarily work well in the video domain, while at the same time they do not take advantage of the extra information present in the video (*e.g.,* tracking already detected regions). Moreover, the quality of the image is generally worse than static images, due to motion blur and out of focus issues, while video compression might create further artefacts. Due to these interferences, methods designed for still images, may fail to obtain reliable detection and recognition results when applied to a video frame. Most importantly, these methods based on image-level can not obtain text tracking information in video. However, spatio-temporal information in video is vital for a number of real-world applications. For example, video understanding and video caption translation all require temporal text information in sequential frames. There have been a few previous works [50, 48] in the community for attempting

Submitted to the 35th Conference on Neural Information Processing Systems (NeurIPS 2021) Track on Datasets and Benchmarks. Do not distribute.

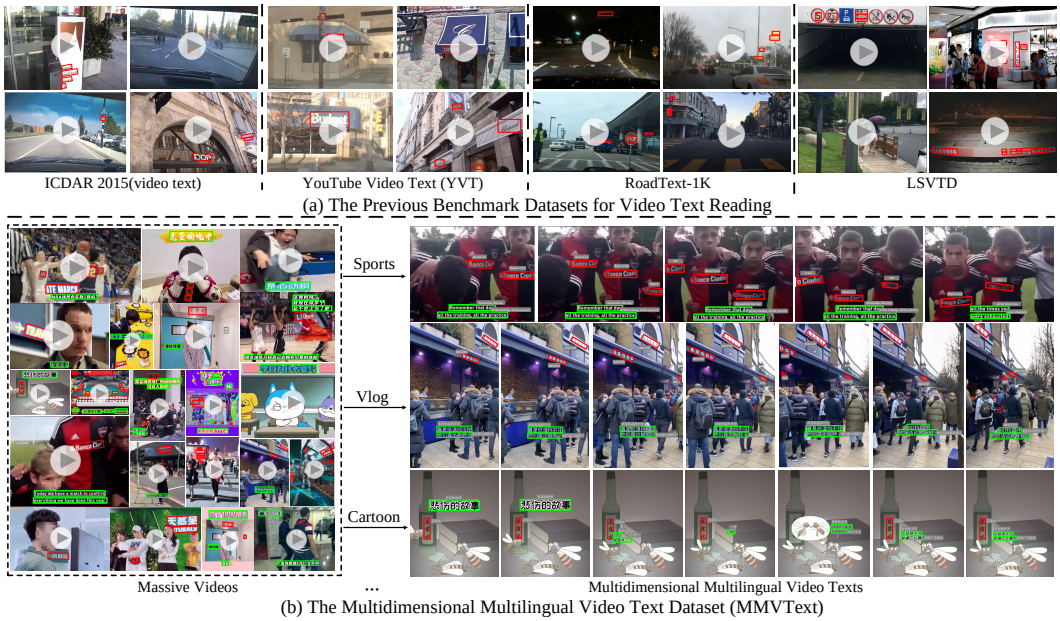

Figure 1: **Example Sequences and Annotations**. Unlike the previous benchmarks, our MMVText contains a wide variety of scenarios and multi-languages. The caption text and scene text are separately tagged for the two different representational meanings.

to develop text reading in videos, and there is a handful of datasets [30, 15] that support the research. ICDAR2015 (Text in Videos) [14], as one of the common datasets, was introduced during the ICDAR Robust Reading Competition in 2015 and mainly includes a training set of 25 videos (13,450 frames in total) and a test set of 24 videos (14,374 frames in total). The videos were categorized into seven scenarios: walking outdoors, searching for a shop in a shopping street, browsing products in a supermarket, etc. YouTube Video Text (YVT) [30] dataset harvested from YouTube, contains 30 videos (13,500 frames in total), 15 for training, and 15 for testing. The text content in the dataset can be divided into two categories, overlay text (*e.g.,* captions, songs title, logos) and scene text (*e.g.,* street signs, business signs, words on shirt). RoadText-1K [31] are sampled from BDD100K [52], includes 700 videos (210,000 frames) for training and 300 videos for testing. The texts in the dataset are all obtained from driving videos and match for driver assistance and self-driving systems. LSVTD [5] includes 100 text videos, 13 indoor (*e.g.,* bookstore, shopping mall) and 9 outdoor (*e.g.,* highway, city road) scenarios. The existing video text benchmarks are limited by the amount of training data (less than 300k frames) and tedium data scenarios, as shown in Figure. 1 (a). There are only a few outdoor scene text videos with 13k frames in ICDAR2015 (video text). Similar situation for YVT, RoadText-1k and LSVTD, the training set is limited and the dataset scenarios are tedious. This makes it difficult to evaluate the effectiveness of more advanced deep learning models.

To address this issue, our work intends to contribute a large-scale, multidimensional multilingual benchmark dataset (MMVText) to the community for developing and testing video text reading systems that can fare in a realistic setting. Our dataset has several advantages. Firstly, the large training set (*i.e.,* 1,010,848 video frames) enables the development of deep design specific for video text spotting. Secondly, MMVText is a multilingual multidimensional dataset. Abundant videos in various scenarios (*e.g.,* driving, street view, news reports, cartoon) are provided for representing real-world scenarios, as shown in Figure. 1 (b). Thirdly, caption and scene text are separately tagged for the two different representational meanings in the video. This is in favor of other tasks, such as video understanding and video retrieval. The main contributions of this work are three folds:

- We propose a large-scale, multidimensional, and multilingual video text spotting benchmark named MMVText. The proposed dataset span various video scenarios, text types, multi-stage tasks and is four times the existing largest dataset.
- Caption text and scene text are separately tagged for the two different representational meanings in the video. Based on the previous works [35, 16], this favors other tasks theoretically, such as video understanding, video retrieval, and video text translation.

- We evaluate the current state-of-the-art techniques for scene text detection, recognition, text tracking, and end-to-end video text spotting. Besides, a thorough analysis of performance on this dataset is provided.

2 Related Work

2.1 End-to-End Text Spotting

For image-level text spotting, various methods [17, 10, 24] based on deep learning have been proposed and have improved the performance considerably. Li et al. [17] proposed the first end-to-end trainable scene text spotting method. The method successfully uses a RoI Pooling [32] to joint detection and recognition features via a two-stage framework. Liao et al. [24] propose a Mask TextSpotter which subtly refines Mask R-CNN and uses character-level supervision to detect and recognize characters simultaneously. However, these methods based on the static image can not obtain temporal information in the video, which is essential for some downstream tasks such as video understanding.

Compared to text spotting in a static image, video text spotting methods are rare. Yin et al. [51] provides a detailed survey, summarizes text detection, tracking and recognition methods in video and their challenges. Wang et al. [46] introduced an end-to-end video text recognition method. Multi-frame text tracking is employed through associations of texts in the current frame and several previous frames to obtain final results. Cheng et al. [5] propose a video text spotting framework by only recognizing the localized text one-time. Nguyen et al. [30] improves detection and recognition performance by temporal redundancy and linearly interpolate to recover missing detection results. Rong et al. [34] tracked video text using tracking-by-detection. An MSER detector was used to locate scene text character (STC), which was used as a constraint to optimize the trajectory search. To promote text spotting in the video, we attempt to establish a standardized evaluation and benchmark (MMVText), covering various open scenarios and multilingual text annotation.

2.2 Text Spotting Datasets for Static Images

The various and practical benchmark datasets [14, 41, 15, 6] contribute to the huge success of scene text detection and recognition at the image level. ICDAR2015 [14] was provided from the ICDAR2015 Robust Reading Competition, which is commonly used for oriented scene text detection and spotting. Google glasses capture these images without taking care of position, so text in the scene can be in arbitrary orientations. ICDAR2017MLT [29] is a large-scale multilingual text dataset, which is composed of complete scene images which come from 9 languages, and text regions in this dataset can be in arbitrary orientations, so it is more diverse and challenging. ICDAR2013 [15] is a dataset proposed in the ICDAR 2013 Robust Reading Competition, which focuses on horizontal text detection and recognition in natural images. The COCO-Text dataset [41] is currently the largest dataset for scene text detection and recognition. It contains 50,000+ images for training and testing. The COCO-Text dataset is very challenging since the text in this dataset is in arbitrary orientation.

2.3 Text Spotting Datasets for Videos

The development of video text spotting is limited in recent years due to the lack of efficient data sets. ICDAR 2015 Video [15] consists of 28 videos lasting from 10 seconds to 1 minute in indoors or outdoors scenarios. Limited videos (*i.e.,* 13 videos) used for training and 15 for testing. Minetto Dataset [27] consists of 5 videos in outdoor scenes. The frame size is 640 x 480 and all videos are used for testing. YVT [30] contains 30 videos, 15 for training and 15 for testing. Different from the above two datasets, it contains web videos except for scene videos. USTB-VidTEXT [50] with only five videos mostly contain born-digital text (captions and subtitles) sourced from Youtube. RoadText-1K provides a driving videos dataset with 1000 videos. The 10-second long video clips in the dataset are sampled from BDD100K [52]. As shown in Table. 1, the existing datasets contain a limited training set and tedium video scenarios. To promote the development of video text spotting and extension of application based on video text, we create a large scale, multidimensional and multilingual dataset, and attempt to provide a more reasonable metric.

Figure 2: **Distributions of MMVText**. (a) Chinese caption and English scene text. (b) Only Chinese caption. (c) Multilingual caption and English scene text. (d) The benchmark dataset covers a wide and open range of life scenes (30 categories) with multilingual texts. Caption text (blue box) and scene text (red box) are distinguished in MMVText, which is favorable for downstream tasks.

3 MMVText Benchmark

This section firstly introduces the collection and annotation of MMVText and provides a comprehensive analysis and comparison. And then, the related tasks and corresponding metrics are described. Finally, we discuss the link to application scenarios and potential impacts.

3.1 Data Collection and Annotation

Data Collection. To obtain abundant and various text videos, we first start by acquiring a large list of text videos class using *KuaiShou*[1] - an online resource that contains billions of videos with various scene text from cartoon movies to human relation. Then, we choose 30 live video categories, *i.e.,* , *E-commerce*, *Game*, *Home*, *Fashion*, and *Technology*, as shown in Figure. 2 (d). With each raw video category, we first choose the video clips with text, then make two rounds of screening to remove the ordinary videos. As a result, we obtain 512 videos with $1,010,848$ video frames, as shown in Table 1. Finally, to fair evaluation, we divide the dataset into two parts: the training set with $641,049$ frames from 331 videos, and the testing set with $369,799$ frames from 179 videos. As shown in Figure 2 (a), different from the existing data sets, which only focus on one type of video text and the video scene is limited, our dataset not only care about scene text spotting in the real world, but also focus on caption texts in the video. For the most part, caption text represents more global information than scene text, which is quite favorable for some downstream tasks, *e.g., video understanding, video caption translation.* Therefore, the MMVText can cover a wider and open range of life scenes, and contains various text with a more comprehensive description of the video.

Data Annotation. We invite a professional annotation team to label each video text with four kinds of description information: the bounding box describing the location information, judging the tracking identification (ID) of the same text instance, identifying the content of the text information, and distinguishing the category label of the caption or scene text. To save the annotation cost, we first sample the videos, annotate each sampled video frame at an instance level, and then transform the annotation information from the sampled video frame to the unlabeled video frame by interpolation. Finally, we invite an audit team to carry out another round of annotation checks, and re-label part video frames with unqualified annotation. *For video sampling*, we use uniform sampling with a sampling frequency of 7 to sample all the videos in the dataset, and obtain the sampled video frame set. *For sampling video frame annotation*, each text instance is labeled in the same quadrilateral way as in the ICDAR 2015 incidental text dataset [55]. In addition, the text instance also will be marked with two description information: the category of the caption or scene, and the recognition content. After the spatial location, content, and category of the video text are determined, the annotator will

Table 1: **Statistical Comparison.** Comparisons between MMVText and existing datasets for caption and scene text in videos. *D, R, T, and S* denotes the Detection, Recognition, Tracking, and Spotting respectively. 'Incidental' denotes indoor and outdoor scenarios in daily life (*e.g., walking outdoors, driving)*. 'Open' refers to any scenarios, e.g., *Game, Sport(NBA).*

Dataset	Category	MLingual	Scenario	Videos	Frames	Texts	Task
AcTiV-D [53]	Caption	-	News video	8	1,843	5,133	D
UCAS-STLData [4]	Caption	-	Teleplay	3	57,070	41,195	D
USTB-VidTEXT [50]	Caption	-	Web video	5	27,670	41,932	D&S
YVT [30]	Both	-	Incidental	30	13,500	16,620	D&R&T&S
ICDAR 2015 VT [55]	Scene	-	Incidental	51	27,824	143,588	D&R&T&S
LSVTD [5]	Scene	✓	Incidental	100	66,700	569,300	D&R&T&S
RoadText-1K [31]	Scene	-	Driving	1000	300,000	1,280,613	D&R&T&S
MMVText (ours)	Both	✓	Open	510	**1,010,848**	**4,513,525**	D&R&T&S

determine the tracking ID by browsing the length of the same video text in the continuous sampling video frames. We also invited other text-related people to conduct two rounds of cross-checking to ensure the annotation quality. *For interpolation on unlabeled video frames*, each text instance is marked with tracking ID and recognition content, so we can judge whether the texts in adjacent sampling frames are the same text with the same ID. For the same text instance, we first determine whether the text annotation of the sampled video frame is the starting and end frame of the text instance. If not, we look forward and backward for the starting and end position of the text instance and label it. Then we use the linear interpolation way to calculate the position of the text object in the middle of the unmarked video frame, and give tracking ID, recognition content, and category. *For check and re-label bad cases,* the linear interpolation shows a dissatisfied performance in some cases, *e.g., the new text appears on starting frame, text suddenly disappears on ending frame,* which are difficult to capture. Therefore, we invite an audit team to carry out another round of annotation checks. Around 150,000 video frames with unqualified annotation from 1,010,848 video frames are selected to refine, taking 20 men in three weeks. As a labor-intensive job, the whole labeling process takes 30 men in two months, *i.e.,* 20,160 man-hours, to complete about 200,000 sampled video frame annotations.

3.2 Dataset Analysis

Statistic Comparison. The qualitative and statistic comparison between the established MMVText and other datasets are visualized in Figure. 1, and summarized in Table. 1. *Category* denotes the category of the text type in the corresponding dataset. *MLingual* denotes whether the dataset contains multiple language texts. *Scenario* denotes the scene range of the video. *Videos, Frames, Texts* represents the number of videos, video frames, video texts in the dataset, respectively. *Task* denotes which tasks the dataset supports. **Caption Text and Scene Text.** For comprehensive evaluation and research, we not only expand the scale of the dataset (*i.e.,* , the number of videos, video frame, and video text), and label the spatial quadrilateral position, recognition content, and tracking ID, but also additionally collect and annotate the category of caption or scene for each text instance. As shown in Figure. 2 (a), in a video, different types of text instances may exist simultaneously, and they are helpful to understand videos synergistically. Concretely, caption text can directly show the dialogue between people in video scenes and represent the time or topic of the video scenes, scene text can unambiguously define the object and can identify important localization and road paths in video scenes. Besides, nowadays, caption text frequently exists in all kinds of life scenarios video. Even for some videos, without any scene texts, there is a lot of caption text, as shown in Figure. 2 (b). To favor downstream tasks (*e.g.,* video text translation, video understanding, and video retrieval), we also provide multilingual text annotations, as shown in Figure. 2 (c).

To provide the community with unified text-level quantitative descriptions, and facilitate controlled evaluation for different approaches, we will compare our dataset with caption or scene text datasets from four aspects, *i.e.,* text description, video scene, dataset size, and supported tasks. *For text description attribute* (*i.e., Category, MLingual*), our MMVText contains both types (caption and scene) of video text and has multi-language features, which obviously has more extensive description ability than caption or scene text dataset. *For video scene attribute* (*i.e., Scenario*), the caption text datasets choose videos with certain professional purposes (*e.g.,* news reports, TV dramas, and

documentaries), which shows that the scenes they cover are relatively limited. And the existing scene text datasets often choose some video scenes captured by mobile shooting, and the number of collectors is small, the range of captured scenes is also limited. However, the videos in our dataset are from videos uploaded voluntarily by all kinds of users. Therefore, the proposed MMVText covers various scenarios, but it also brings significant challenges to researchers. *For the size of the dataset*(*i.e., Videos, Frames, Texts*), we can find that our MMVText has advantages over the superimposed caption text dataset and the scene text dataset in the indicators of videos, frames, and texts. The number of videos in RoadText-1K is more than ours (*1,000 vs. 510*), but the number of frames in RoadText-1K is far less than ours (*300,000 vs. 1,010,848*), which imply that the average video length of RoadText-1K is much shorter than ours (*300 vs. 1,982*). *For the supported tasks*, the proposed MMVText supports four common video text tasks: detection, recognition, video text tracking, end to end video text spotting. The focus and application scenarios of each task is entirely different. For example, detection task used in the static image focus on localization performance, paving the way for recognition task, which apply to license plate recognition. End to end video text spotting task focuses on recognition and tracking performance, which apply to video understanding and video retrieval. In conclusion, the high efficiency of MMVText for evaluating advanced deep learning methods is very favorable for promoting various text spotting applications in real life.

3.3 MMVText Tasks and Metrics

Standardized benchmark metrics are crucial as same as the dataset for the majority of computer vision applications, and we attempt to provide a reasonable evaluation for video text spotting methods. The proposed MMVText includes four tasks: (1) Text Detection. (2) Text Recognition. (3) Video Text Tracking, aimed at describing text location information in continuous frames. (4) End to End Text Spotting in Videos, to understand text and track multiple frames.

Following ICDAR2015 [55], The evaluation protocol [44] was be used for text detection and recognition task. For video text tracking task, the existing video text tracking datasets such as ICDAR2015 (video) [15] and RoadText-1k [31] all adopted the MOT metrics (*i.e.,* Multiple Object Tracking Accuracy ($MOTA$) and Multiple Object Tracking Precision ($MOTP$)). However, there are two sets of measures for Multiple Object Tracking: the MOT metrics ($MOTA$,$MOTP$) [2] and ID metrics (ID_{F1}) [18, 33]. The CVPR19 MOTChallenge evaluation framework [7] presents that different measures serve different purposes. $Event\text{-}based$ measures like MOT help pinpoint the source of some errors, and are thereby informative for the designer of certain system components. $Identity\text{-}based$ measure(ID_{F1}) is more favorable for evaluating how well computed identities conform to true identities. Therefore, except for using the standard measures(MOTA, MOTP), $Identity\text{-}based$ measures(ID_{F1}), as a new metric is adopted firstly for video text spotting task. ID_{F1} is the ratio of correctly identified detections over the average number of ground-truth and computed detections. And the metric is more reasonable to evaluate ID switches in some cases. We also evaluate the metrics in MMVText by:

$$ID_{F1} = \frac{2ID_{tp}}{2ID_{tp} + ID_{fp} + ID_{fn}}, \tag{1}$$

where ID_{tp}, ID_{fp} and ID_{fn} refer to true positive, false positive and false negative of matching ID. Besides, the ID metric [7] also includes MT (Mostly Tracked) Number of objects tracked for at least 80 percent of lifespan, ML (Mostly Lost) Number of objects tracked less than 20 percent of lifespan.

For Task4 (End to End Text Spotting in Videos), the objective of this task is to recognize words in the video as well as localize them in terms of time and space. And we argue that the final recognition result is more important than text localization in videos. Thus, we modify the ID_{F1} to TID_{F1}, which focuses on text instance ID tracking and recognition results that be required by many downstream tasks. More specifically,

$$TID_{tp} = \sum_{h} \sum_{t} m(h, o, \triangle_t, \triangle_s, \triangle_r), \tag{2}$$

$$TID_{F1} = \frac{2TID_{tp}}{2TID_{tp} + TID_{fp} + TID_{fn}}, \tag{3}$$

where $\triangle_t$, $\triangle_s$ and $\triangle_r$ refer to ID matching, space location matching and recognition result matching. h and o denote hypothesis set (*e.g.,* predicted ID I_p , box locations L_p, recognition results R_p) and

ground truth set with (ID I_g, box locations L_g, recognition ground true R_g). And the three matching can be obatined by:

$$\triangle_t : I_p = I_g, \quad \triangle_s : I_p = I_g, \quad \triangle_r : I_p = I_g. \tag{4}$$

The match of h and o is a true positives of text ID (*i.e.,* TID_{tp}) when these conditions (*i.e.,* $\triangle_t$:$I_p = I_g$, $\triangle_s$:$IoU(L_p, L_g) > 0$ and $\triangle_r$:$R_p = R_g$) are met. Similarly, false positive (*i.e.,* TID_{fp}) and false negative (*i.e.,* TID_{fn}) of text ID can be obtained for TID_{F1} calculation. More details concerning metrics in supplarmentary material.

3.4 Methods

Text detection and recognition in the static image have made tremendous progress, and abundant great work [45, 54, 36] be proposed. By contrast, the counterparts in video text reading are rare and lack quality open-source algorithms. Therefore, we adopt various mature techniques in the static image to better evaluate the efficiency of MMVText.

Detection. The deep learning-based text detection methods can be roughly divided into two categories: regression-based method and segmentation-based method. EAST [54] as one of the popular regression-based methods is used to test our MMVtext. The method adopts FCNs to predict shrinkable text score maps, rotation angles and perform per-pixel regression, followed by a post-processing NMS. For segmentation based methods, we adopt PSENet [45] and DB [20] to evaluate our MMVtext. PSENet [45] generates various scales of shrinked text segmentation maps, then gradually expands kernels to generate the final instance segmentation map. Similarly, DB [20] utilizes the shrinked text segmentation maps and differentiable binarization to detect text instances. **Recognition**. Recent methods mainly use two techniques to train the scene text recognition model, namely Connectionist Temporal Classification (CTC) and attention mechanism. In CTC-based methods, CRNN [36] as the representation, which introduced CTC decoder into scene text recognition with a Bidirectional Long Short-Term Memory (BiLSTM) to model the feature sequence. In Attention-based methods, RARE [37] firstly normalizes the input text image using the Spatial Transformer Network (STN [12]), then utilizes CNN to extract feature and captures the contextual information within a sequence of characters. Finally, it estimates the output character sequence from the identified features with the attention module.

Text Tracking Trajectory Generation. With text detection and recognition in a static image, we only obtain text localization and recognition information without temporal information, which are insufficient for video spotting evaluation (*e.g.,* TID_{F1},$MOTA$ and $MOTP$). The work [46] based on multi-frame tracking provides a method to track text instances temporally based on attributes of the text objects in multiple frames. Following the work [46], we link and match text objects in the current frame and several frames by IOU and edit distance of text.

4 Experimental

In this section, we conduct experiments on our MMVText to demonstrate the effectiveness of the proposed benchmark. Note that we denote Ground Truth of ID tracking in all the experiments, Mostly Tracked and Mostly Lost as 'GT', 'MT' and 'ML', respectively.

4.1 Implementation Details

All of the experiments use the same strategy: (1) Training detector and recognizer with MMVText. (2) Matching text objects with corresponding text tracking trajectory id. *Detection*: without pretrained model, we train detectors directly with training set (*i.e.,* 641,049 frame images) of MMVText. *Recognition*: the network is pre-trained on the *chinese ocr*[2] and MJSynth [11], and further fine-tuned on our MMVText. All of our experiments are conducted on 8 V100 GPUs. PSENet [45], EAST [54] and DB [20] are adopted as the base detectors because of their popularity. CRNN [36] and RARE [37] as the base text recognizers to evaluate our MMVText. In the PSENet, EAST, DB, CRNN and RARE experiments, all settings follow the original reports.

(a) Tracking of Different Scenario (b) Video Text Spotting of Different Scenario (c) Recognition of Different Languages (d) Detection of Different Text Category

Figure 3: **Attribute Experiments of MMVText**. (a) Tracking performance (*i.e.,* ID_{F1}) with EAST [54] in different scenarios. (b) End to end video text spotting performance (*i.e.,* TID_{F1}) with PSENet [45] and CRNN [36] in different scenarios. (c) Recognition accuracy of different models in different languages. (d) Detection performance of different model in caption or scene text. 'CH', 'AN' and 'ALL' refer to 'Chinese Characters', 'Alphanumeric Characters' and 'All Characters'.

4.2 Attribute Experiments Analysis

Text Tracking in Different Scenarios. Figure. 3 (a) gives the tracking performance ID_{F1} of EAST [54] in different scenarios of MMVText. The model achieves the best performance with a ID_{F1} of 57% in cartoon videos, since the conspicuous text instances and simple background are designed in cartoon videos. By comparison, several scene categories obtain extremely dissatisfied performance due to complex background and various text appearance, such as $Campus$ and $Travel$.

New Scenarios, New Challenge for Text Spotting. Figure. 3 (b) gives the end-to-end performance TID_{F1} using PSENet [45] as the detector and CRNN [36] as the recognizer in different scenarios of MMVText. Similar to tracking performance using EAST [54], the end-to-end video spotting performance shows the best performance with a TID_{F1} of 31% in scenario of $Cartoon$. Outdoor scenes video (e.g., Campus, Travel, Celebrity) usually have a more complex environment and unsteady camera movement. On the contrary, some easy video types such as cartoons hardly contain complex scene text, and the camera movement extremely stable by manual handling.

Multilingual Recognition, New Challenge. As shown in Figure. 3 (c), the text recognition results for different languages are provided. In summary, the alphanumeric recognition result (about 47%) is better than the Chinese recognition result (about 35%), regardless of the models. The final results (about 40%) for all characters are satisfactory, can not meet the requirement of the application. Unlike English(26 characters), Chinese contains thousands of characters(3,856 Chinese characters v.s. 26 English characters on MMVText), which are difficult to recognize. As shown in Figure. 6, we argue that many clear image patches with Chinese text still bring recognition errors, since the classification of such many characters is difficult for the network to learn. By comparison, most English errors are caused by blur and out-of-focus.

Long Caption Text, New Challenge for Text Detection. As shown in Figure. 3 (d), we provide the detection performance comparison for different models in different text categories (*i.e.,* caption text or scene text) of MMVText. It is obvious that the performance for scene text is better than the counterpart of caption text, regardless of which detection model. The prime reason is that caption texts are all long text, a different case to detect without any model refinement.

4.3 Text Detection and Recognition in Images

Although text detection and recognition in static images are not the focus in this work, we provide the corresponding performance for comparison, as shown in Table. 2. For text detection, we adopts EAST [54], PSENet [45] and DB [20] to evaluate the proposed MMVText. We observe that frame-level text detection and recognition results on MMVText are not unsatisfactory, with lower results than these methods report on existing scene text datasets. For example, EAST only obtains an f-score of 44.1% compared to the F-score of 80.7% on icdar2015 [55]. For text recognition, CRNN [36] based

Table 2: **Detection and Recognition Performance on MMVText**. Frame level text Detection and Recognition performance of existing models on MMVText. 'CH', 'AN' and 'ALL' refer to 'Chinese Characters', 'Alphanumeric Characters' and 'All Characters'.

Detection Performance/%				Recognition Performance/%								
Method	Precision	Recall	F-score	Method	Pretrained				Fine tuned			
					CH	AN	EN	ALL	CH	AN	EN	ALL
EAST	52.2	38.1	44.1	CRNN	26.0	32.1	36.1	23.2	33.2	47.1	49.5	38.6

DB	77.2	64.5	70.3	GRCNN	23.1	39.8	40.4	26.7	35.6	49.2	52.4	40.3

Figure 4: **Bad cases for multilingual text recognition**. The incorrectly recognized characters are marked in red. '[ ]' denotes the prediction of the corresponding character is missing.

on CTC loss, RARE [37] with attention mechanism and GRCNN [43] as the base text recognizers to test our MMVText. The text annotation in our MMVText covers two languages (*i.e.,* English and Chinese), thus we conduct several experiments for each language. 'CH' and 'AN' refer to Chinese text instances and alphanumeric characters. 'ALL' denotes all characters regardless of which language. Similar to the detection task, the recognition model only yields about 40% accuracy on our dataset, but the same model reports $> 90+$ on most benchmark datasets [15] for scene text recognition. The main reasons have two points: (1) The proposed MMVText is multilingual, and the category number of Chinese characters in real-world images is much larger than those of Latin languages. (2) The video texts are quite blurred, out-of-focus, and the distribution of characters is relatively smaller than the static image counterparts.

4.4 Text Tracking and Spotting in Videos

Video Text Tracking. Table. 3 shows the comparing results of text tracking on MMVText. We observe that the overall performances of the used detectors are dissatisfactory on MMVText. Besides, the IDF_1 of EAST [54] is lower with 6.7% gap than that of PSENet [45]. The main reason is that MMVTtext contains a mass of long text instances, but regression-based EAST can not deal with the long text cases well. The performance of DB is similar to that of PSENet for both all are the segmentation-based methods. According to Table. 3, $MOTP$ shows a better performance than $MOTA$. We argue that detectors such as PSENet or DB provide strong detecting capacity, but the tracking ability is relatively weak. By comparison, IDF_1 is a comprehensive metric for object ID tracking. $\mathrm{ID}_{\mathrm{F1}}$ (31.7%) of DB achieves the best performance of the three detectors, and EAST shows the worst performance with a $\mathrm{ID}_{\mathrm{F1}}$ of 23.2%.

End to End Text Spotting in Video. Detection or text tracking tasks are paving the way for the recognition task. Table. 4 shows the performance of text spotting in the video. And TID_{F1} in Equation. 10 as an integrated metric to evaluate algorithms in spatial location, content, and temporal information three dimensions. Similar to the text tracking performance of EAST, the corresponding

Table 3: **Text Tracking Performance on MMVText.** Text tracking trajectory id generation use a method proposed in [46].

Method	MOTP	MOTA	ID_P/%	ID_R/%	ID_{F1}/%	GT	MT	ML
EAST [54]	0.275	-0.301	23.5	22.9	23.2	48321	20.1%	74.2%
PSENet [45]	0.112	0.334	34.7	26.7	29.9	48321	26.4%	69.1%
DB [20]	0.102	0.438	33.7	29.9	**31.7**	48321	30.1%	65.1%

Table 4: **End to End Video Text Spotting Performance on MMVText.** Text tracking trajectory id generation use a method proposed in [46]. TID_P, TID_R, TID_{F1}, $MOTP_T$ and $MOTA_T$ refer to the corresponding metrics with recognition results in Table. 3.

Method		TID_P/%	TID_R/%	TID_{F1}/%	MOTA_T	MOTP_T	MT	ML
Detection	Recognition							
EAST [54]	CRNN [36]	5.3	5.1	5.2	-0.835	0.173	3.2%	95.0%
	RARE [37]	3.0	3.6	3.2	-1.130	0.173	2.6%	95.4%
PSENet [45]	CRNN [36]	14.7	9.8	11.8	-0.300	0.197	7.8%	88.9%
	RARE [37]	15.2	10.4	12.4	-0.280	0.201	8.0%	87.8%
DB [20]	CRNN [36]	15.6	9.6	11.9	-0.284	0.230	6.9%	89.5%
	RARE [37]	20.1	15.2	**17.3**	-0.293	0.150	8.7%	82.0%

performance TID_{F1} using CRNN [36] as the recognizer in video text spotting is still not satisfied with a 5.2% TID_{F1}. The combination of DB [20] and RARE [37] achieves the best performance with a 17.3% TID_{F1} among all the cases, but the performance still is inadequate to meet application requirements. MT (Mostly Tracked) and ML (Mostly Lost) as the metrics concerning statistical number can be used to evaluate from another aspect. For the combination of DB [20] and RARE [37], 39650 text tracking trajectories are lost, less than 20 percent of lifespan. By comparison, only 4230 tracking trajectories are satisfactory, more than 80 percent of lifespan tracked.

4.5 Discussion for Real Applications

Text spotting in static images has numerous application scenarios: (1) Automatic data entry. SF-Express [3] utilizes OCR techniques to accelerate the data entry process. NEBO [4] performs instant transcription as the user writes down notes. (2) Autonomous vehicle [26, 25]. Text-embedded panels carry important information, *e.g.,* geo-location, current traffic condition, navigation, and etc. (3) Text-based reading comprehension. TextCaps [38] and text-based VQA [39, 3] show the new vision-and-language tasks, which need to recognize text, relate it to its visual context, semantic, and visual reasoning between multiple text tokens and visual entities, such as objects. Similarly, there are many application demands for video text understanding across various industries and in our daily lives. We list the most outstanding ones that significantly impact, improving our productivity and life quality. **Firstly**, automatically describing video with natural language [49, 47] can bridge video and language. **Secondly**, video text automatic translation [5] can be extremely helpful as people travel, and help video-sharing websites [6] to cut down language barriers. **Finally,** text-based video retrieval [16, 21] is a irreplaceable business for many companies, such as Google and YouTube. More details and analyses for application scenarios concerning MMVText in the supplementary material.

4.6 Potential Negative Societal Impacts

We argue that there mainly exits slight potential negative societal impacts for personal privacy. Although much personal information, *e.g., names, identifying information, human faces*, have been blurred to protect privacy, there still might exist a little risk.

5 Conclusion and Future Work

In this paper, we establish a large-scale multidimensional and multilingual dataset for video text tracking and spotting, termed as MMVText, with four description information, *i.e.,* , bounding box, tracking ID, recognition content, and text category label. Compare with the existing benchmarks, the proposed MMVText mainly contains three advantages: large-scale, multidimensional, multilingual. MMVText spans various video scenarios, text types, and multi-stage tasks, promoting video text research. We also conduct several experiments on this dataset and shed light on what attributes are especially difficult for the current task, which cast new insight into the video text tracking, spotting field. In general, we hope the MMVText would facilitate the advance of video-and-text research.

A Appendix

A.1 MMVText Metrics

The proposed MMVText mainly includes two tasks: (1) Video Text Tracking. (2) End to End Text Spotting in Videos. $MOTP$ (Multiple Object Tracking Precision) [2], $MOTA$ (Multiple Object Tracking Accuracy) and IDF_1 [7, 33] as the three important metrics are used to evaluate task1 (text tracking) for MMVText. Following the previous works [15, 31], MMVText evaluates text tracking methods in video and compare their performance with the MOTA and MOTP, which are given by:

$$MOTP = \frac{\sum_{i,t}(1 - d_t^i)}{\sum_t c_t}, \tag{5}$$

where c_t denotes the number of matches found for time t. For each of these matches, calculate the iou d_t^i between the object o^i and its corresponding hypothesis. It shows the ability of the tracker to estimate precise object positions. MOTA is calculated as follows:

$$MOTA = 1 - \frac{\sum_t(m_t + fp_t + mme_t)}{\sum_t g_t}, \tag{6}$$

where m_t, fp_t and mme_t are the number of misses, false positives, and mismatches, respectively. g_t is the number of objects present at time t. It shows the tracker's performance at detecting objects and

keeping their trajectories, independent of the precision of the location. Besides, ID_{F1} as the new metrics for tracking is calculated as follows:

$$ID_{tp} = \sum_{h} \sum_{t} m(h, o, \triangle_t, \triangle_s)\,, \tag{7}$$

$$ID_{F1} = \frac{2ID_{tp}}{2ID_{tp} + ID_{fp} + ID_{fn}}\,, \tag{8}$$

where $\triangle_t$ and $\triangle_s$ refer to time matching and space location matching, respectively. ID_{tp}, ID_{fp} and ID_{fn} refer to true positive, false positive and false negative of matching ID.

In Task2 (End to End Text Spotting in Videos), we modify the $MOTA$, $MOTA$ and ID_{F1} to $MOTA_T$, $MOTA_T$ and TID_{F1}, the only difference is the matches need to meet the correct of the recognition result, since the recognition result is more important than tracking and localization. More specifically, TID_{F1} is calculated as follows:

$$TID_{tp} = \sum_{h} \sum_{t} m(h, o, \triangle_t, \triangle_s, \triangle_r)\,, \tag{9}$$

$$TID_{F1} = \frac{2TID_{tp}}{2TID_{tp} + TID_{fp} + TID_{fn}}\,, \tag{10}$$

where $\triangle_t$, $\triangle_s$ and $\triangle_r$ refer to time matching, space location matching and recognition result matching. And h and o denote hypothesis and true text trajectory with recognition result. The match of h and o is a true positives of text ID (*i.e.,* TID_{tp}) when these conditions (*i.e.,* $\triangle_t$, $\triangle_s$ and $\triangle_r$) are met. Similarly, false positive (*i.e.,* TID_{fp}) and false negative (*i.e.,* TID_{fn}) of text ID can be obtained for TID_{F1} calculation.

A.2 Link to Real Applications

In this section, we show that the practicability of the proposed MMVText, not a toy benchmark, which can promote other video-and-text application research.

Video Understanding. As shown in Figure. 5 (a), the example concerning the task of describing video with natural language is from MSR-VTT [49], and there has been increasing interest in video understanding [47, 19]. However, video description with only visual information is difficult and limited, even for a human. For the annotation of the sample video, *i.e., "A man in a blue suit and purple tie discusses millennial investing fear"*, we can not learn the information of "millennial investing fear" from the visual information in the video. By comparison, caption and scene texts in the video contain accurate information of *"millennial investing fear"*, which can help the model to describe the video better. We argue that the same as general human understanding, videos without captions and audio, is difficult to be properly understood by the model. We hope the release of MMVText can promote efficient video text reading, further enhancing automatic video description.

Video Text Automatic Translation. Another practical application is video text automatic translation, as shown in Figure. 5 (b). The application may be unnecessary for several professional teams or classic movies due to the professional translator or huge cost investment. But for international video-sharing websites [7] [8] with millions of users, it isn't easy to apply multilingual caption and scene text in billions of videos. Therefore, efficient translation concerning caption text (e.g., overlap, song title, logos) and scene text (e.g., street signs, business signs, words on shirt) still need further exploration and research. The large-scale and multilingual MMVText contributes various real scenarios for the development of video text automatic translation.

Video Retrieval. Video retrieval with textual cues [28, 42] is also a very important application direction for video-and-text research, as shown in Figure. 5 (c). To the best of my knowledge, video retrieval with text information in the video is still almost a blank field of study and immature application in the industry. The most existing video retrieval methods are stiff combinations of text detection and recognition, invalid for the example with a sentence query. Besides, similar to video

[8] https://www.kuaishou.com/en

Figure 5: **The Real Application Tasks Link to MMVText**. (a) Video Understanding, automatically describing visual content with natural language. (b) Video Caption Translation, extremely helpful for people who travel abroad and video-sharing websites such as YouTube. (c) Video Retrieval, accurate semantic information for text in videos can promote video retrieval.

understanding, for the query of the sample video, *i.e., "The lakers play host to Golden State"*, we can not obtain the correct related video without scene text or caption information. The missing information needs to recover by understanding the video with key video text information such as *"GOLDEN STATE WARRIORS, LOS ANGELES LAKERS"*. The proposed MMVText with various text types (*e.g.,* caption, song title, logos, street signs, business signs) and annotation can promote the research concerning efficient video retrieval.

A.2.1 Limitations

Although the proposed MMVText supports all video text spotting tasks, *i.e., text detection, recognition, tracking end to end video text spotting*, the potential contributions for other tasks still need mining. For example, as shown in Figure. 5 (c), we do not provide the corresponding annotation (*i.e.,* the query for each video) and metrics concerning video retrieval, but the annotation and metric are easy to obtain due to text spotting annotation already existed. Therefore, there are still many potential contributions for other tasks on MMVText, we want to take these as the future research directions and provide a complete solution method.

A.3 More statistical information for MMVText.

Checklist

1. For all authors...
   (a) Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope? [Yes]

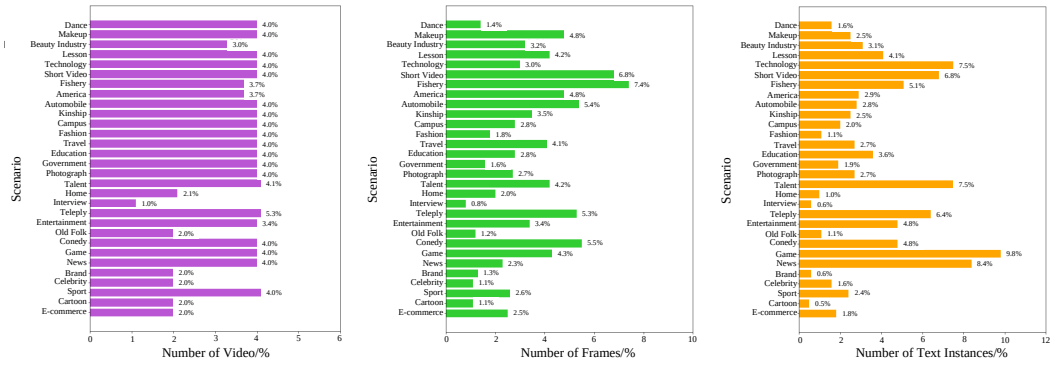
Table 5: **The Data Distribution for 30 Open Scenarios**. Red refers to these scenarios only supported by MMVText. "%" denotes the percentage of each scenario data for whole data.



(a) Video Distribution of Different Scenario (b) Frames Distribution of Different Scenario (c) Text Distribution of Different Scenario

Figure 6: **The Data Distribution for 30 Open Scenarios**. (a) Video distribution for different scenarios. (b) Video frames distribution for different scenarios. (c) Text instance distribution for different scenarios.

(b) Did you describe the limitations of your work? [Yes] We describe the limitations in supplementary material.

(c) Did you discuss any potential negative societal impacts of your work? [Yes]

(d) Have you read the ethics review guidelines and ensured that your paper conforms to them? [Yes]

2. If you are including theoretical results...

(a) Did you state the full set of assumptions of all theoretical results? [N/A]

(b) Did you include complete proofs of all theoretical results? [N/A]

3. If you ran experiments (e.g. for benchmarks)...

(a) Did you include the code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL)? [Yes] We have provided the URL concerning the coding and the data to promote further research.

(b) Did you specify all the training details (e.g., data splits, hyperparameters, how they were chosen)? [Yes]

(c) Did you report error bars (e.g., with respect to the random seed after running experiments multiple times)? [Yes]

(d) Did you include the total amount of compute and the type of resources used (e.g., type of GPUs, internal cluster, or cloud provider)? [Yes]

4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets...

(a) If your work uses existing assets, did you cite the creators? [Yes]

(b) Did you mention the license of the assets? [Yes]

(c) Did you include any new assets either in the supplemental material or as a URL? [Yes]

	Languages			Text Category	
	English	Chinese	Alphanumeric	Caption Text	Scene Text
Video	GT 141(27.6%)	432(84.7%)	158(31.0%)	389(76.3%)	359(70.4%)
Video Frames	325,739(32.2%)	856,504(85.8%)	367,991(36.4%)	803,382(79.5%)	542,380(53.7%)
Text Instances	1,364,690(30.2%)	3,057,751(67.8%)	1,455,774(32.2%)	2,182,474(48.4%)	2,331,051(51.6%)

Table 6: **Statistics of text language and category in MMVText.**

(d) Did you discuss whether and how consent was obtained from people whose data you're using/curating? [N/A]

(e) Did you discuss whether the data you are using/curating contains personally identifiable information or offensive content? [Yes] We have blurred identifiable information or offensive content.

5. If you used crowdsourcing or conducted research with human subjects...

(a) Did you include the full text of instructions given to participants and screenshots, if applicable? [Yes]

(b) Did you describe any potential participant risks, with links to Institutional Review Board (IRB) approvals, if applicable? [N/A]

(c) Did you include the estimated hourly wage paid to participants and the total amount spent on participant compensation? [Yes] We have paid salary to the related participants.
